

Pin diagram of 8086 microprocessor

The Intel 8086 is 40 pin DIP Microprocessor. Here we will see the actual pin level diagram of 8086 MPU.

8086 was the first 16-bit microprocessor available in 40-pin DIP (Dual Inline Package) chip. Let us now discuss in detail the pin configuration of a 8086 Microprocessor.

This is the actual pin diagram of 8086 Microprocessor.

Now let us see the Pin functions of the 8086 microprocessor.

Pins	Function
AD₁₅ – AD₀	These are 16 address/data bus. AD0-AD7 carries low order byte data and AD8AD15 carries higher order byte data. During the first clock cycle, it carries 16-bit address and after that it carries 16-bit data.
A₁₆ – A₁₉	These are the 4 address/status buses. During the first clock cycle, it carries 4-bit address and later it carries status signals.
V_{cc}	It uses 5V DC supply at V _{CC} pin 40
GND	These are ground at V _{SS} pin 1 and 20.
Clock	Clock signal is provided through Pin-19. It provides timing to the processor for operations. Its frequency is different for different versions, i.e. 5MHz, 8MHz and 10MHz.
S7/BHE	BHE stands for Bus High Enable. It is available at pin 34 and used to indicate the transfer of data using data bus D8-D15. This signal is low during the first clock cycle, thereafter it is active.
Read($\overline{\text{RD}}$)	It is available at pin 32 and is used to read signal for Read operation.
Ready	It is available at pin 32. It is an acknowledgement signal from I/O devices that data is transferred. It is an active high signal. When it is high, it indicates that the device is ready to transfer data. When it is low, it indicates wait state.
RESET	It is available at pin 21 and is used to restart the execution. It causes the processor to immediately terminate its present activity. This signal is active high for the first 4 clock cycles to RESET the microprocessor.
INTR	It is available at pin 18. It is an interrupt request signal, which is sampled during the last clock cycle of each instruction to determine if the processor considered this as an interrupt or not.
NMI	It stands for non-maskable interrupt and is available at pin 17. It is an edge triggered input, which causes an interrupt request to the microprocessor.
$\overline{\text{TEST}}$	This signal is like wait state and is available at pin 23. When this signal is high, then the processor has to wait for IDLE state, else the execution continues.
MN/$\overline{\text{MX}}$	It stands for Minimum/Maximum and is available at pin 33. It indicates what mode the processor is to operate in; when it is high, it works in the minimum mode and vice-versa.
INTA	It is an interrupt acknowledgement signal and is available at pin 24. When the microprocessor receives this signal, it acknowledges the interrupt.
ALE	It stands for address enable latch and is available at pin 25. A positive pulse is generated each time the processor begins any operation. This signal indicates the availability of a valid address on the address/data lines.
DEN	It stands for Data Enable and is available at pin 26. It is used to enable Transceiver 8286. The transceiver is a device used to separate data from the address/data bus.

Pins	Function
DT/R	It stands for Data Transmit/Receive signal and is available at pin 27. It decides the direction of data flow through the transreceiver. When it is high, data is transmitted out and vice-a-versa.
M/IO	This signal is used to distinguish between memory and I/O operations. When it is high, it indicates I/O operation and when it is low indicating the memory operation. It is available at pin 28.
WR	It stands for write signal and is available at pin 29. It is used to write the data into the memory or the output device depending on the status of M/IO signal.
HLDA	It stands for Hold Acknowledgement signal and is available at pin 30. This signal acknowledges the HOLD signal.
HOLD	This signal indicates to the processor that external devices are requesting to access the address/data buses. It is available at pin 31.
QS₁ and QS₀	These are queue status signals and are available at pin 24 and 25. These signals provide the status of instruction queue.
S₀, S₁, S₂	These are the status signals that provide the status of operation, which is used by the Bus Controller 8288 to generate memory & I/O control signals. These are available at pin 26, 27, and 28.
LOCK	When this signal is active, it indicates to the other processors not to ask the CPU to leave the system bus. It is activated using the LOCK prefix on any instruction and is available at pin 29.
RQ/GT₁ and RQ/GT₀	These are the Request/Grant signals used by the other processors requesting the CPU to release the system bus. When the signal is received by CPU, then it sends acknowledgment. RQ/GT ₀ has a higher priority than RQ/GT ₁ .

There are some conditions for QS₀ and QS₁. These conditions are as follows.

QS₀	QS₁	Status
0	0	No operation
0	1	First byte of opcode from the queue
1	0	Empty the queue
1	1	Subsequent byte from the queue

The S₂, S₁ and S₀ are the status signals. Here is a list of status and their bit patterns.

S₂	S₁	S₀	Status
0	0	0	Interrupt acknowledgement
0	0	1	I/O Read
0	1	0	I/O Write
0	1	1	Halt
1	0	0	Opcode fetch
1	0	1	Memory read
1	1	0	Memory write
1	1	1	Passive
